The software installs all drivers and [The influence of extracellular matrix proteins on the process of muscle differentiation]. It is well-known that skeletal muscle differentiation is dependent on the presence of mechanical forces, but the influence of other extracellular matrix (ECM) proteins on the myogenic process is unclear. We used chick embryo myoblasts in the presence of the following ECM proteins: fibronectin, laminin, collagen I, collagen IV, and collagen I gel. We studied the regulation of the myogenic process and its morphological changes. Our results showed that the addition of all studied proteins enhances myoblast differentiation. These data demonstrate that components of ECM may play an important role in myogenesis. This effect may be mediated via the formation of cell membrane contact. Furthermore, ECM proteins seem to influence the processes of myogenic differentiation by modifying the cytoskeleton architecture and the formation of focal adhesions.
